The medication used for lipolysis injections is a liver protection medication known for many years now; it is also applied to prevent fat embolism in blood.

Up to date, however, it has not yet been approved for lipolysis injections.

For this reason, there exist special patient information requirements with respect to the application.

The experienced physicians affiliated with NETWORK-Lipolysis are available to advise you thoroughly.

Against the background of many thousands of treatments in the whole world no serious side-effects have been observed up to now. Nevertheless, the therapy must be carried out by medical experts trained in this field.

In order to make the therapy a success a knowledge about fat deposits in the body, the correct injection technique and the right dosage for the treatment that seems to be so simple is of utmost importance.

You will find this Leaflet exclusively in the practices of physicians having obtained the certification for lipolysis injections. These physicians are the persons you can trusting turn to.
Injection Lipolysis

Simply melting superfluous fat away by means of an injection – a fascinating idea. During this procedure the substance phosphatidylcholine (PPC) is directly injected into undesired fat deposits. The active substance is a natural compound made from the soybean. The body itself uses to produce this substance in the same composition in order to have multiple tasks performed, especially in the field of fat metabolism. Dr. Hasengschwandtner of Austria, our Medical and Scientific Director of NETWORK-Lipolysis, proceeded with the development of this therapy. Apart from reducing undesired side-effects Dr. Hasengschwandtner and his team in particular succeeded in improving treatment results considerably. Meanwhile, the members of the NETWORK have carried out some thousands of treatments and have gathered a lot of experience with the specialized NETWORK injection lipolysis.

Fat deposits slowly fade away

Lipolysis injections must not be regarded as a new miracle drug for weight reduction. But when it comes to fat deposits which cannot be eliminated by nutritional therapy or concerted therapeutic exercises lipolysis injections initiate a process during which fat is melted away and then eliminated from the body via the usual metabolic process. The medication is directly injected into the area concerned. As a result, fat cells start to melt away and are eliminated to an increasing degree. And due to its elasticity, the skin contracts to build a smooth homogenous surface.

Areas qualified for treatment are:

**Face**
- double chin
- jowls

**Body**
- gluteofemoral adiposity (saddlebags)
- inner thigh
- lower buttocks / transition to thigh
- love handles (with men)
- hips
- upper and lower belly
- fat bulges at shoulder-arm-joints
- upper arm
- knees
- dorsal areas

Treatment of cellulite

- thighs

Lipoma

As a rule, 2–4 treatments in intervals of 6–8 weeks are necessary to finish the therapy with success.

More than 80% of the patients are very satisfied with the results after 2–3 treatments.

Risks of the Therapy

The fact that lipolysis injections have not yet been officially approved as a therapy is to be regarded as a general risk. But it is not the only therapy successfully applied without official approval. A well-known example for millions of treatments over many years without approval are the botulinum toxin injections for the treatment of furrows.

Health risks, however, have not been observed by the members of NETWORK-Lipolysis. The active substance itself and its elimination from the body via metabolism is no problem at all and has generally been investigated and documented.

Almost every patient shows some temporary side-effects after treatment like redness, swelling and muscle ache-like discomfort and – in some cases – hematomas. After a few days, however, any discomfort at the treated region will have disappeared.

Please obtain information about the individual and general side-effects and risks from your physician during a comprehensive personal conversation.
